# Regular Planar Tilings

## Why are there only 3 regular tilings?

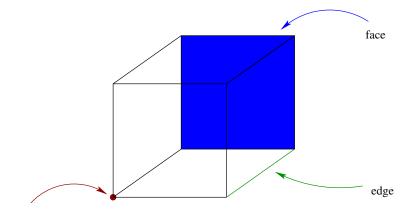

A convex polyhedron is *regular* if all of the bounding polygons are congruent regular polygons and if each vertex is adjacent to the same number of bounding polygons.

#### A regular convex polyhedron is known as a Platonic Solid.

There are 5 Platonic solids.

# parts of polyhedra

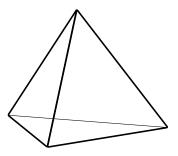

vertex

#### Platonic solid: Tetrahedron

A tetrahedron has 4 faces which are equilateral triangles.

It has 4 vertices (each touching 3 faces).

It has 6 edges.

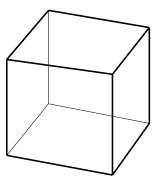

#### Platonic solid: Cube

A cube has 6 faces which are squares.

It has 8 vertices (each touching 3 faces).

It has 12 edges.

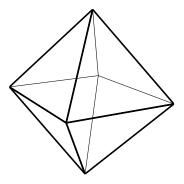

#### Platonic solid: Octahedron

An octahedron has 8 faces which are equilateral triangles.

It has 6 vertices (each touching 4 faces).

It has 12 edges.

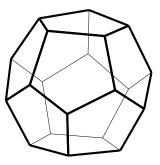

#### Platonic solid: Dodecahedron

An dodecahedron has 12 faces which are regular pentagons.

It has 20 vertices (each touching 3 faces).

It has 30 edges.

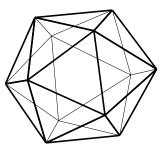

#### Platonic solid: Icosahedron

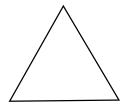

An icosahedron has 20 faces which are equilateral triangles.

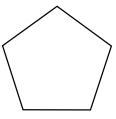

It has 12 vertices (each touching 5 faces).

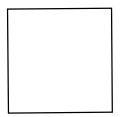

It has 30 edges.

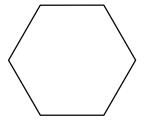

# Regular Polygons (again)

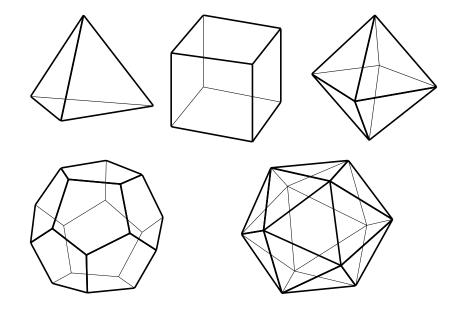

Why are there only 5 Platonic solids?

If F is the number of Faces of a polyhedron, E is the number of Edges and V is the number of vertices, then the value of

$$F - E + V$$

is called the *Euler characteristic* of the polyhedron.

## A look at the Euler characteristic of Platonic solids

| Solid        | Faces | Edges | Vertices | Euler characteristic |
|--------------|-------|-------|----------|----------------------|
| tetrahedron  |       |       |          |                      |
| cube         |       |       |          |                      |
| octahedron   |       |       |          |                      |
| dodecahedron |       |       |          |                      |
| icosahedron  |       |       |          |                      |

## Euler Characteristic

The Euler Characteristic of all convex polyhedra is 2.

#### SemiRegular Polyhedra

A convex polyhedron is *semiregular* if all of the bounding polygons are regular polygons (possibly more than one type) with edges the same length and if each vertex is adjacent to the same number of bounding polygons, and there exists a fixed cyclic orderof the types of polygons around all the vertices.

#### Archimedean Solids

#### There are 13 Archimedean solid which are semiregular polyhedra.

All prisms and antiprisms are semiregular polyhedra.

A rhombicuboctahedron is an Archimedean solid. It has 24 vertices, each which meets 3 squares and one triangle. How many faces does it have? How many edges does it have? A truncated icosidodecahedron is an Archimedean solid. It has 30 square faces, 20 hexagonal faces and 12 decagonal faces. How many vertices does it have? How many edges does it have? Make your own polyhera models
